The database server is important but it's just one component of a complete SQL Server environment. It's also a great idea to consider a deployment that provides high availability (HA), typically by way of replication. Replication allows you to have continuous availability of the data across multiple database servers. When you failover a database server, SQL Server can continue to replicate the data to the standby server to keep the databases synchronized. Replication also provides some features that are useful in a disaster recovery (DR) plan. In this column, we'll look at the basic concepts of SQL Server replication and how it can be used. When SQL Server 2016 is released, replication will be one of the features added to SQL Server Management Studio, in the same manner as table and indexes and other database objects. It's also possible to use replication to replicate entire databases or just tables to a remote server. This type of replication is generally better suited for disaster recovery purposes. Using the Replication Agent Replication, in its simplest form, is a way for one server to automatically send data changes to a second server. If you wanted to replicate a table in a database, then you would write a custom T-SQL script (or you could use SSIS, or any other tool to accomplish the same thing) that would connect to the source server and make the changes. Then you would use a SQL statement to synchronize the data to the target database. Replication can be asynchronous or synchronous. In asynchronous replication, the target database server performs a series of changes and receives the results asynchronously. As you can imagine, there's a lag time and the target database server will not always have the most up-to-date information. With synchronous replication, the target server applies the same database changes at the same time, thus ensuring that it always has the most recent information. A synchronization error will also result in the target server being stuck with the previous database state. Replication, when it comes to data and tables, can be either transactional or non-trans

1. A Macro is a programming code that is repeatedly executed. 2. Macros are an invaluable tool for database developers who must prepare SQL scripts for multiple applications. It automates the development process by creating macros from SQL statements and executing them automatically. Macros can be invoked using any combination of statements with different functions. The possibilities are endless, allowing them to be created for virtually every application. The developed macros are saved as standalone (.mcl) files for easy execution. You can easily find and execute the macros within the program itself. Requirements: 1. Object-Oriented Technology: Macros can be created using any object-oriented programming language. SQL statements, SQL functions, user-defined functions, and other macros can be called directly from macro programs. 2. Macros can be created using any platform that is compatible with the programming language, regardless of the platform or device where the macro is executed. 3. Macros can be created using any version of Microsoft SQL Server. Description of Object-Oriented Technology: Object-Oriented Technology is a discipline that allows one to design, develop, and deploy software systems by creating objects, then connecting these objects together to create a structure. The first step is creating an object, then creating connections that are made by one object to another object. Four levels are used to connect these objects together: i) Data Access Object. ii) Structure Object. iii) Aggregate Object. iv) Application Object. How to create a Macro: To create a macro, follow the steps below: Step 1. Create the Project: 1) Create a macro project. 2) Select the project file type. 3) Select the macro project file type. 4) Click Next to create the project. Step 2. Select the Database: 1) Create a database project. 2) Select the database file type. 3) Select the database file type. 4) Click Next to create the project. Step 3. Select the Object: 1) Select the object you wish to use for the macro. 2) Select the macro object to be created. 3) Select the macro. 4) Click Next. Step 4. Create the Function: 1) Select the function you wish to create. 2) Select the function type. 3) Select the function type. 4) Click Next. 5. Create the SQL 77a5ca646e
